

Ecommerce Project

In our project we use HTML,CSS & Java Script

-First page is registration page

In this page we ask user to enter some pieces of data
(name,email,password,phone,birthdate,city)

We use local storage to store email and password

For user if he clicked remember me

-Second page is login page

User can not access this page if he has no account

-Third page is Home page

In home page we show main categories of the products

Depending on API from “fakestoreapi”

Hint (data limited in this api only 20 products/4 categories)

We render the data dynamic from JS using (CloneNode)

There are 4 categories in each category there are some products

When we click on product image we go to its product and we show
the products according to which category is clicked (not more one
page)

Stars which indicate rat its value generated randomly

For each category when we clicked -shop now- button, we show
this product's information
